

ACPL-P343 and ACPL-W343

4.0-A Output Current IGBT Gate Drive Optocoupler with Rail-to-Rail Output Voltage in Stretched SO6

Description

The Broadcom[®] ACPL-P343 and ACPL-W343 contain an AlGaAs LED, which is optically coupled to an integrated circuit with a power output stage.

This optocoupler is ideally suited for driving power IGBTs and MOSFETs used in motor control inverter applications. The high operating voltage range of the output stage provides the drive voltages required by gate controlled devices. The voltage and high peak output current supplied by this optocoupler make it ideally suited for direct driving IGBT with ratings up to 1200V/200A.

For IGBTs with higher ratings, this optocoupler can be used to drive a discrete power stage which drives the IGBT gate. The ACPL-P343 and ACPL-W343 have the highest insulation voltage in the IEC/EN/DIN EN 60747-5-5:

- ACPL-P343: $V_{IORM} = 891V_{peak}$
- ACPL-W343: $V_{IORM} = 1140V_{peak}$

Features

- 4.0-A maximum peak output current
- 3.0-A minimum peak output current
- Rail-to-rail output voltage
- 200-ns maximum propagation delay
- 100-ns maximum propagation delay difference
- LED current input with hysteresis
- 35 kV/ μ s minimum Common Mode Rejection (CMR) at $V_{CM} = 1500V$
- $I_{CC} = 3.0$ mA maximum supply current
- Under voltage lock-out protection (UVLO) with hysteresis
- Wide operating V_{CC} range: 15V to 30V
- Industrial temperature range: $-40^{\circ}C$ to $105^{\circ}C$
- Safety approval:
 - UL Recognized 3750/5000 V_{RMS} for 1 min.
 - CSA
 - IEC/EN/DIN EN 60747-5-5 $V_{IORM} = 891/1140V_{peak}$

Applications

- IGBT/MOSFET gate drive
- AC and brushless DC motor drives
- Renewable energy inverters
- Industrial inverters
- Switching power supplies

CAUTION! It is advised that normal static precautions be taken in handling and assembly of this component to prevent damage and/or degradation that may be induced by ESD. The components featured in this data sheet are not to be used in military or aerospace applications or environments.

Functional Diagram

NOTE: A 1- μ F bypass capacitor must be connected between pins V_{CC} and V_{EE} .

Truth Table

LED	$V_{CC} - V_{EE}$ Positive Going (Turn On)	$V_{CC} - V_{EE}$ Negative Going (Turn Off)	V_O
OFF	0V to 30V	0V to 30V	Low
ON	0V to 12.1V	0V to 11.1V	Low
ON	12.1V to 13.5V	11.1V to 12.4V	Transition
ON	13.5V to 30V	12.4V to 30V	High

Ordering Information

ACPL-P343 is UL Recognized with 3750 V_{RMS} for 1 minute per UL1577.

ACPL-W343 is UL Recognized with 5000 V_{RMS} for 1 minute per UL1577.

Part Number	RoHS Compliant Option	Package	Surface Mount	Tape and Reel	IEC/EN/DIN EN 60747-5-5	Quantity
ACPL-P343	-000E	Stretched SO-6	X	—	—	100 units per tube
ACPL-W343	-500E		X	X	—	1000 units per reel
	-060E		X	—	X	100 units per tube
	-560E		X	X	X	1000 units per reel

To order, choose a part number from the part number column and combine it with the desired option from the option column to form an order entry.

Example 1: Select ACPL-P343-560E to order the product consisting of a Stretched SO-6 Surface Mount package in Tape and Reel packaging, with IEC/EN/DIN EN 60747-5-5 Safety Approval that is RoHS compliant.

Example 2: Select ACPL-W343-000E to order the product consisting of a Stretched SO-6 Surface Mount package in Tube packaging that is RoHS compliant.

Option data sheets are available. Contact your Broadcom sales representative or authorized distributor for information.

ACPL-W343 Stretched SO-6 Package: 8-mm Clearance

Solder Reflow Temperature Profile

Recommended reflow condition as per JEDEC Standard, J-STD-020 (latest revision). Use non-halide flux.

Regulatory Information

The ACPL-P343 and ACPL-W343 are approved by the following organizations:

UL	Recognized under UL 1577, component recognition program up to $V_{ISO} = 3750V_{RMS}$ (ACPL-P343) and $V_{ISO} = 5000V_{RMS}$ (ACPL-W343) expected prior to product release.
CSA	CSA Component Acceptance Notice #5, File CA 88324
IEC/EN/DIN EN 60747-5-5 (Option 060 Only)	Maximum Working Insulation Voltage $V_{IORM} = 891V_{peak}$ (ACPL-P343) and $V_{IORM} = 1140V_{peak}$ (ACPL-W343)

IEC/EN/DIN EN 60747-5-5 Insulation Characteristics: Option 060

a. Refer to IEC/EN/DIN EN 60747-5-5 Optoisolator Safety Standard section of the *Broadcom Regulatory Guide to Isolation Circuits*, AV02-2041EN, for a detailed description of Method a and Method b partial discharge test profiles.

NOTE: These optocouplers are suitable for “safe electrical isolation” only within the safety limit data. Maintenance of the safety data shall be ensured by means of protective circuits. Surface-mount classification is Class A in accordance with CECC 00802.

Insulation-Related and Safety-Related Specifications

Parameter	Symbol	ACPL-P343	ACPL-W343	Units	Conditions
Minimum External Air Gap (External Clearance)	L(101)	7.0	8.0	mm	Measured from input terminals to output terminals, shortest distance through air.
Minimum External Tracking (External Creepage)	L(102)	8.0	8.0	mm	Measured from input terminals to output terminals, shortest distance path along body.
Minimum Internal Plastic Gap (Internal Clearance)	—	0.08	0.08	mm	Through insulation distance conductor to conductor, usually the straight line distance thickness between the emitter and detector.
Tracking Resistance (Comparative Tracking Index)	CTI	>175	>175	V	DIN IEC 112/VDE 0303 Part 1
Isolation Group	—	IIIa	IIIa	—	Material Group (DIN VDE 0110, 1/89, Table 1)

NOTE: All Broadcom data sheets report the creepage and clearance inherent to the optocoupler component itself. These dimensions are needed as a starting point for the equipment designer when determining the circuit insulation requirements. However, once mounted on a printed circuit board, minimum creepage and clearance requirements must be met as specified for individual equipment standards. For creepage, the shortest distance path along the surface of a printed circuit board between the solder fillets of the input and output leads must be considered (the recommended land pattern does not necessarily meet the minimum creepage of the device). There are recommended techniques such as grooves and ribs which may be used on a printed circuit board to achieve desired creepage and clearances. Creepage and clearance distances will also change depending on factors, such as pollution degree and insulation level.

Absolute Maximum Ratings

Parameter	Symbol	Min.	Max.	Units	Note
Storage Temperature	T_S	-55	125	°C	
Operating Temperature	T_A	-40	105	°C

a. Maximum pulse width = 50 μs .

b. Output is sourced at -3.0A with a maximum pulse width = 10 μs . $V_{CC} - V_O$ is measured to ensure 15V or below.

c. Output is sourced at 3.0A with a maximum pulse width = 10 μs . $V_O - V_{EE}$ is measured to ensure 15V or below.

d. Output is sourced at -3.0A/3.0A with a maximum pulse width = 10 μs .

e. In this test, V_{OH} is measured with a DC load current. When driving capacitive loads, V_{OH} will approach V_{CC} as I_{OH} approaches 0 amps.

f. Maximum pulse width = 1 ms.

Switching Specifications (AC)

Unless otherwise noted, all typical values are at $T_A = 25^\circ\text{C}$, $V_{CC} - V_{EE} = 30\text{V}$, $V_{EE} = \text{Ground}$; all minimum and maximum specifications are at recommended operating conditions ($T_A = -40^\circ\text{C}$ to 105°C , $I_{F(\text{ON})} = 7\text{ mA}$ to 16 mA , $V_{F(\text{OFF})} = -3.6\text{V}$ to 0.8V , $V_{EE} = \text{Ground}$, $V_{CC} = 15\text{V}$ to 30V).

Parameter	Symbol	Min.	Typ.	Max.	Units	Test Conditions	Figure	Note
Propagation Delay Time to High Output Level	t_{PLH}	50	98	200	ns	$R_g = 10\Omega$, $C_g = 25\text{ nF}$, $f = 20\text{ kHz}$, Duty Cycle = 50%, $I_F = 7\text{ mA}$ to 16 mA , $V_{CC} = 15\text{V}$ to 30V	14, 15, 16, 17, 18, 26	
Propagation Delay Time to Low Output Level	t_{PHL}	50	95	200	ns			
Pulse Width Distortion	PWD	—	22	70	ns			a
Propagation Delay Difference Between Any Two Parts	PDD ($t_{\text{PHL}} - t_{\text{PLH}}$)	-100	—	100	ns		33, 34	b
Rise Time	t_R	—	43	—	ns	$V_{CC} = 30\text{V}$	26	
Fall Time	t_F	—	40	—	ns			
Output High Level Common Mode Transient Immunity	$ CM_H $	35	50	—	kV/ μs	$T_A = 25^\circ\text{C}$, $I_F = 10\text{ mA}$, $V_{CC} = 30\text{V}$, $V_{CM} = 1500\text{V}$ with split resistors	27	c,d
Output Low Level Common Mode Transient Immunity	$ CM_L $	35	50	—	kV/ μs			$T_A = 25^\circ\text{C}$, $V_F = 0\text{V}$, $V_{CC} = 30\text{V}$, $V_{CM} = 1500\text{V}$ with split resistors

- Pulse Width Distortion (PWD) is defined as $|t_{\text{PHL}} - t_{\text{PLH}}|$ for any given device.
- The difference between t_{PHL} and t_{PLH} between any two ACPL-P343 parts under the same test condition.
- Pin 2 must be connected to LED common.
- Common mode transient immunity in the high state is the maximum tolerable dV_{CM}/dt of the common mode pulse, V_{CM} , to assure that the output will remain in the high state (that is, $V_O > 15.0\text{V}$).
- Common mode transient immunity in a low state is the maximum tolerable dV_{CM}/dt of the common mode pulse, V_{CM} , to assure that the output will remain in a low state (that is, $V_O < 1.0\text{V}$).

Package Characteristics

Unless otherwise noted, all typical values are at $T_A = 25^\circ\text{C}$; all minimum/maximum specifications are at recommended operating conditions.

Parameter	Symbol	Device	Min.	Typ.	Max.	Units	Test Conditions	Note

Application Information

Product Overview Description

The ACPL-P343 and ACPL-W343 are optically isolated power output stages capable of driving IGBTs of up to 200A and 1200V. Based on BCDMOS technology, these gate drive optocouplers deliver higher peak output current, better rail-to-rail output voltage performance, and two times faster speed than the previous generation of products.

The high peak output current and short propagation delay are needed for fast IGBT switching to reduce dead time and improve system overall efficiency. Rail-to-rail output voltage ensures that the IGBT gate voltage is driven to the optimum intended level with no power loss across IGBT. This helps the designer lower the system power, which is suitable for bootstrap power supply operation.

It has very high common mode rejection (CMR) rating which allows the microcontroller and the IGBT to operate at very large common mode noise found in industrial motor drives and other power switching applications. The input is driven by direct LED current and has a hysteresis that prevents output oscillation if insufficient LED driving current is applied. This will eliminate the need of additional Schmitt trigger circuit at the input LED.

The stretched SO6 package, which is up to 50% smaller than conventional DIP package, facilitates a smaller, more compact design. These stretched packages are compliant to many industrial safety standards, such as IEC/EN/DIN EN 60747-5-5, UL 1577, and CSA.

Recommended Application Circuit

The recommended application circuit shown in [Figure 28](#) illustrates a typical gate drive implementation using the ACPL-P343. The following describes driving the IGBT, however, it is also applicable to MOSFET. Designers will need to adjust the V_{CC} supply voltage, depending on the MOSFET or IGBT gate threshold requirements (recommended $V_{CC} = 15V$ for IGBT and 12V for MOSFET).

The 1- μ F supply bypass capacitors provide the large transient currents necessary during a switching transition. Because of the transient nature of the charging currents, a low-current (3.0 mA) power supply will be enough to power the device. The split resistors (in the ratio of 1.5:1) across the LED will provide a high CMR response by providing a balanced resistance network across the LED.

The gate resistor R_G serves to limit gate charge current and controls the IGBT collector voltage rise and fall times.

In PC board design, care should be taken to avoid routing the IGBT collector or emitter traces close to the ACPL-P343 input as this can result in the unwanted coupling of transient signals into ACPL-P343 and degrade performance.

Figure 28: Recommended Application Circuit with Split Resistors LED Drive

Rail-to-Rail Output

Figure 29 shows a typical gate driver's high current output stage with 3 bipolar transistors in darlington configuration. During the output high transition, the output voltage rises rapidly to within 3 diode drops of V_{CC} . To ensure the V_{OUT} is at V_{CC} in order to achieve IGBT rated $V_{CE(ON)}$ voltage. The level of V_{CC} will need to be raised to beyond $V_{CC}+3(V_{BE})$ to account for the diode drops. And to limit the output voltage to V_{CC} , a pull-down resistor, $R_{PULL-DOWN}$ between the output and V_{EE} is recommended to sink a static current while the output is high.

ACPL-P343 uses a power PMOS to deliver the large current and pull it to V_{CC} to achieve rail-to-rail output voltage as shown in Figure 30. This ensures that the IGBT gate voltage is driven to the optimum intended level with no power loss across IGBT even when an unstable power supply is used.

Figure 29: Typical Gate Driver with Output Stage in Darlington Configuration

Figure 30: ACPL-P343/W343 with PMOS and NMOS Output Stage for Rail-to-Rail Output Voltage

Selecting the Gate Resistor (Rg)

1. Calculate Rg minimum from the IOL peak specification. The IGBT and Rg in Figure 28 can be analyzed as a simple RC circuit with a voltage supplied by ACPL-P343/ACPL-W343.

$$\begin{aligned} R_g &\geq (V_{CC} - V_{EE} - V_{OL}) / I_{OLPEAK} \\ &= (15V + 5V - 2.9V) / 4A \\ &= 4.3\Omega \approx 5\Omega \end{aligned}$$

The V_{OL} value of 2.9V in the previous equation is the V_{OL} at the peak current of 4.0A (see Figure 7).

2. Check the ACPL-P343/ACPL-W343 power dissipation and increase Rg if necessary. The ACPL-P343/ACPL-W343 total power dissipation (P_T) is equal to the sum of the emitter power (P_E) and the output power (P_O).

$$P_T = P_E + P_O$$

$$P_E = I_F \times V_F \times \text{Duty Cycle}$$

$$\begin{aligned} P_O &= P_{O(BIAS)} + P_{O(SWITCHING)} \\ &= I_{CC} \times (V_{CC} - V_{EE}) + E_{SW}(R_g; C_g) \times f \end{aligned}$$

Using I_F (worst case) = 16 mA, $R_g = 5\Omega$, Max Duty Cycle = 80%, $C_g = 25$ nF, $f = 25$ kHz and T_A max = 85°C:

$$P_E = 16 \text{ mA} \times 1.95V \times 0.8 = 25 \text{ mW}$$

$$\begin{aligned} P_O &= 3 \text{ mA} \times 20V + 5 \text{ mJ} \times 25 \text{ kHz} \\ &= 60 \text{ mW} + 125 \text{ mW} \end{aligned}$$

$$= 185 \text{ mW} < 700 \text{ mW } (P_{O(MAX)} @ 85^\circ\text{C})$$

The value of 3 mA for I_{CC} in the previous equation is the maximum I_{CC} over the entire operating temperature range.

Since P_O is less than $P_{O(MAX)}$, $R_g = 5\Omega$ is all right for the power dissipation.

Figure 31: Energy Dissipated in the ACPL-P343/W343 for Each IGBT Switching Cycle

LED Drive Circuit Considerations for High CMR Performance

Figure 32 shows the recommended drive circuit for the ACPL-P343 and ACPL-W343 that gives optimum common-mode rejection. The two current setting resistors balance the common mode impedances at the LED anode and cathode. Common-mode transients can be capacitive coupled from the LED anode, through CL_A (or cathode through CL_C) to the output-side ground causing current to be shunted away from the LED (which is not wanted when the LED should be on) or conversely cause current to be injected into the LED (which is not wanted when the LED should be off).

Table 1 shows the directions of I_{LP} and I_{LN} depend on the polarity of the common-mode transient. For transients occurring when the LED is on, common-mode rejection (CM_H , since the output is at high state) depends on LED current (I_F). For conditions where I_F is close to the switching threshold (I_{FLH}), CM_H also depends on the extent to which I_{LP} and I_{LN} balance each other. In other words, any condition where a common-mode transient causes a momentary decrease in I_F (that is, when $dV_{CM}/dt > 0$ and $|I_{LP}| > |I_{LN}|$, referring to Table 1) will cause a common-mode failure for transients which are fast enough.

Likewise for a common-mode transient that occurs when the LED is off (that is, CM_L , since the output is at low state), if an imbalance between I_{LP} and I_{LN} results in a transient I_F equal to or greater than the switching threshold of the optocoupler, the transient signal may cause the output to spike above 1V, which constitutes a CM_L failure. The balanced I_{LED} -setting resistors help equalize the common mode voltage change at the anode and cathode. The shunt drive input circuit will also help to achieve high CM_L performance by shunting the LED in the off state.

Figure 32: Recommended High-CMR Drive Circuit for the ACPL-P343/W343

Table 1: Common Mode Pulse Polarity and LED Current Transients

dV_{CM}/dt	I_{LP} Direction	I_{LN} Direction	If $ I_{LP} < I_{LN} $, I_F Is Momentarily	If $ I_{LP} > I_{LN} $, I_F Is Momentarily
Positive (>0)	Away from LED anode through CL_A	Away from LED cathode through CL_C	Increase	Decrease
Negative (<0)	Toward LED anode through CL_A	Toward LED cathode through CL_C	Decrease	Increase

Dead Time and Propagation Delay Specifications

The ACPL-P343/ACPL-W343 includes a Propagation Delay Difference (PDD) specification intended to help designers minimize “dead time” in their power inverter designs. Dead time is the time period during which both the high and low side power transistors (Q1 and Q2 in Figure 28) are off. Any overlap in Q1 and Q2 conduction will result in large currents flowing through the power devices between the high and low voltage motor rails.

To minimize dead time in a given design, the turn on of LED2 should be delayed (relative to the turn off of LED1) so that under worst-case conditions, transistor Q1 has just turned off when transistor Q2 turns on, as shown in Figure 33. The amount of delay necessary to achieve this condition is equal to the maximum value of the propagation delay difference specification, PDD_{MAX}, which is specified to be 100 ns over the operating temperature range of 40°C to 105°C.

Figure 33: Minimum LED Skew for Zero Dead Time

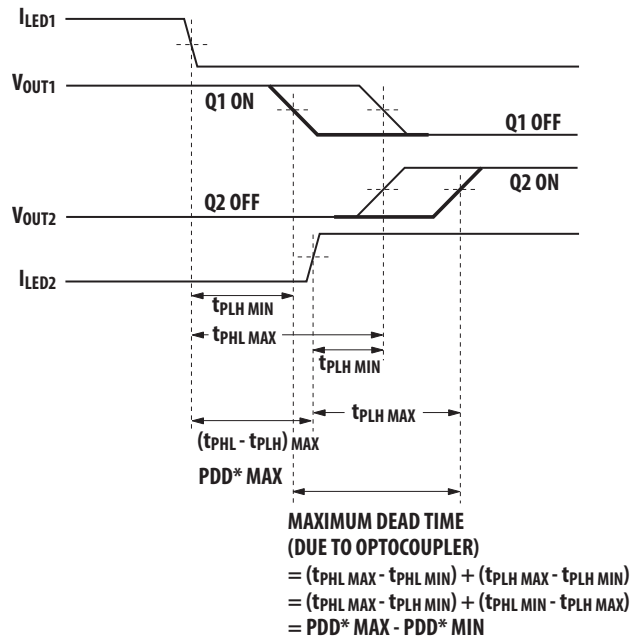

*PDD = Propagation Delay Difference
 Note: for PDD calculations the propagation delays are taken at the same temperature and test conditions.

Delaying the LED signal by the maximum propagation delay difference ensures that the minimum dead time is zero, but it does not tell a designer what the maximum dead time will be. The maximum dead time is equivalent to the difference between the maximum and minimum propagation delay difference specifications as shown in Figure 34. The maximum dead time for the ACPL-P343/ACPL-W343 is 200 ns (= 100 ns – (–100 ns)) over an operating temperature range of –40°C to 105°C.

Note that the propagation delays used to calculate PDD and dead time are taken at equal temperatures and test conditions since the optocouplers under consideration are typically mounted in close proximity to each other and are switching identical IGBTs.

Figure 34: Waveforms for Dead Time

*PDD = Propagation Delay Difference
 Note: For Dead Time and PDD calculations all propagation delays are taken at the same temperature and test conditions.

LED Current Input with Hysteresis

The detector has optical receiver input stage with built in Schmitt trigger to provide logic compatible waveforms, eliminating the need for additional wave shaping. The hysteresis (Figure 12) provides differential mode noise immunity and minimizes the potential for output signal chatter.

Under Voltage Lockout

The ACPL-P343/ACPL-W343 Under Voltage Lockout (UVLO) feature is designed to prevent the application of insufficient gate voltage to the IGBT by forcing the ACPL-P343/ACPL-W343 output low during power-up. IGBTs typically require gate voltages of 15V to achieve their rated $V_{CE(ON)}$ voltage. At gate voltages below 13V typically, the $V_{CE(ON)}$ voltage increases dramatically, especially at higher currents. At very low gate voltages (below 10V), the IGBT may operate in the linear region and quickly overheat. The UVLO function causes the output to be clamped whenever insufficient operating supply (V_{CC}) is applied. Once V_{CC} exceeds V_{UVLO+} (the positive-going UVLO threshold), the UVLO clamp is released to allow the device output to turn on in response to input signals.

Thermal Model for ACPL-P343/ ACPL-W343 Stretched SO6 Package Optocoupler

Definitions

R_{11} : Junction to ambient thermal resistance of LED due to heating of LED

R_{12} : Junction to ambient thermal resistance of LED due to heating of detector (output IC)

R_{21} : Junction to ambient thermal resistance of detector (output IC) due to heating of LED

R_{22} : Junction to ambient thermal resistance of detector (output IC) due to heating of detector (output IC)

P_1 : Power dissipation of LED (W)

P_2 : Power dissipation of detector/output IC (W)

T_1 : Junction temperature of LED ($^{\circ}\text{C}$)

T_2 : Junction temperature of detector ($^{\circ}\text{C}$)

T_a : Ambient temperature

Ambient Temperature

Junction to Ambient Thermal Resistances were measured ~1.25 cm above optocoupler at $\sim 23^{\circ}\text{C}$ in still air.

Thermal Resistance	$^{\circ}\text{C/W}$
R_{11}	135
R_{12}	27
R_{21}	39
R_{22}	47

This thermal model assumes that an 6-pin single-channel plastic package optocoupler is soldered into a 7.62 cm \times 7.62 cm printed circuit board (PCB) per JEDEC standards. Use the following equations to calculate the temperature at the LED and detector junctions of the optocoupler:

$$T_1 = (R_{11} \times P_1 + R_{12} \times P_2) + T_a \quad (1)$$

$$T_2 = (R_{21} \times P_1 + R_{22} \times P_2) + T_a \quad (2)$$

Using the given thermal resistances and thermal model formula in this data sheet, we can calculate the junction temperature for both LED and the output detector. Both junction temperatures should be within the absolute maximum rating. For example, given $P_1 = 25 \text{ mW}$, $P_2 = 185 \text{ mW}$, $T_a = 85^{\circ}\text{C}$:

LED junction temperature:

$$\begin{aligned} T_1 &= (R_{11} \times P_1 + R_{12} \times P_2) + T_a \\ &= (135 \times 0.025 + 27 \times 0.185) + 85 \\ &= 93.4^{\circ}\text{C} \end{aligned}$$

Output IC junction temperature:

$$\begin{aligned} T_2 &= (R_{21} \times P_1 + R_{22} \times P_2) + T_a \\ &= (39 \times 0.025 + 47 \times 0.185) + 85 \\ &= 94.7^{\circ}\text{C} \end{aligned}$$

T_1 and T_2 should be limited to 125°C based on the board layout and part placement.
